

Rasoi — where to put next month's ₹1 crore

Based only on rasoi_growth_data.csv (1 Jun–29 Aug 2026). "Now" = last 28 clean acquisition days scaled to 30 days. ₹L = ₹ lakh.

1. Recommendation

Pause ShareChat video, trim Meta lookalike, and shift budget toward Meta broad, Google UAC (actions), and Meta retargeting. Use cohort-matched first-month net ROAS as the main budget metric, not cost per trial. The modeled plan produces about **₹55.9 lakh** of first-month net revenue on **₹1 crore** spend (ROAS ≈ **0.56**) versus about **₹53.0 lakh** (ROAS ≈ 0.53) under the modeled current mix. The modeled gain is about **+5.4%**; sensitivity is +2.1% to +9.2% for response exponents 0.6–1.0. This is a scenario estimate, not a statistically estimated forecast.

Campaign	Now → proposed	Trials	Paying	Net rev.
Meta broad	₹22.2L → ₹33.3L	13,500	4,170	₹17.0L
Google UAC (actions)	₹14.9L → ₹22.4L	9,299	3,129	₹14.4L
Google UAC (installs)	₹20.1L → ₹21.4L	9,992	2,697	₹9.8L
Meta lookalike 3%	₹23.2L → ₹14.8L	17,194	2,413	₹6.8L
Meta retargeting	₹5.5L → ₹8.2L	4,547	1,616	₹7.9L
ShareChat video	₹7.8L → ₹0.0L	0	0	₹0.0L
Total	₹1,00,00,000	54,532	14,024	₹55.9L

Model: expected trials = current run-rate trials × (proposed spend / current spend)^{0.8}; paying users = trials × 90-day cohort trial→paid; net revenue = trials × 90-day net first-month revenue per trial. The 0.8 exponent is a planning assumption, not estimated from a reliable saturation curve. Each live campaign is constrained to 0.6×–1.5× current run-rate because the file does not support extrapolation far outside observed spend.

2. Evidence

Cost per trial and value produce very different rankings. Meta lookalike has the cheapest trial (₹88) but only 14.0% trial→paid and 8.3% annual mix, producing ₹0.45 net ROAS. Meta retargeting costs ₹159 per trial but converts 35.5%, has 30.2% annual mix, and produces ₹1.10 net ROAS. ShareChat has the cheapest CPI (₹8.4) but the weakest CAC (₹831) and net ROAS (0.34).

Weekly steering metric: cohort-matched first-month net ROAS. It captures conversion, plan mix and refunds in one number, while CAC and annual mix should be watched as early diagnostic indicators because first-month ROAS is inherently lagged.

Diminishing returns: the data suggests diminishing returns may exist, but cannot identify their size reliably. Cost per trial rose by similar amounts where spend growth was small and large, so the increase may reflect creative fatigue or price drift rather than saturation. The 0.8 power curve is therefore an explicit planning assumption.

3. Data issue and treatment

Google UAC (actions) and installs, 19–24 July — 12 rows. Trials collapsed while spend and installs remained broadly normal; renewals and revenue also collapsed. The pattern is consistent with missing trial/billing events, but the CSV cannot prove the root cause. I flag the rows, keep the raw data unchanged, and exclude both the flagged acquisition days and their next-day outcomes from cohort ratios; I do not interpolate values. Engineering should confirm whether trial events were lost or never fired and whether they can be backfilled.

4. Key caveats

ShareChat is the campaign I would pause for the next allocation cycle, pending evidence. I would reverse that decision if a 2–3 week holdout at roughly ₹8 lakh shows first-month net ROAS ≥0.6 or later retention materially improves cumulative economics. Only retargeting clears month-1 break-even in this file; later payback is **not supported by the available data**. Retargeting may include non-incremental conversions and its small audience may not scale 1.5×. The brief says renewals belong to the previous day's trials; the file itself correlates more strongly with same-day trials, so engineering should confirm the event dating. A same-day diagnostic changes CAC by at most ₹6 and ROAS by about 0.004, with rankings unchanged.

Chart takeaway: shift budget toward campaigns with stronger first-month net ROAS and fund those increases from lower-value campaigns; do not use cheap trials as the sole steering signal.
