

Rasoi — supporting answers (Tasks 1–4)

Companion to the one-page recommendation. Source: rasoi_growth_data.csv; figures are reproduced by the revised rasoi_analysis.py.

Task 1 — Can the file be trusted?

Profile: 540 rows × 12 columns = 6 campaigns × 90 days (1 Jun–29 Aug 2026); 3 channels; no missing values, duplicate rows, duplicate date+campaign pairs or calendar gaps. Funnel-order checks pass, refunds do not exceed revenue, all numeric values are non-negative, and revenue matches trials × █1 + monthly renewals × █199 + annual renewals × █1,199 on all 540 rows.

The one real problem: both Google campaigns (gg_uac_actions and gg_uac_installs), 19–24 July 2026, 12 rows. Trials fell about 94% while spend and installs remained broadly normal; renewals and revenue collapsed too. Detection uses each campaign’s trial-per-install ratio against its own median; all 12 flagged rows are far below normal.

Diagnosis: the pattern is consistent with a trial-event/billing tracking issue rather than a real demand collapse, but the CSV cannot establish the root cause. **Treatment:** flag, do not delete or interpolate; keep raw rows; exclude flagged acquisition days and their next-day outcomes from cohort performance ratios, including spend, so a suspected tracking failure is not treated as poor paid-media performance.

Engineering questions: (1) Were 19–24 July trial events lost or never fired, and can they be backfilled? (2) How are renewals dated? (3) How is the █199/█1,199 plan experiment assigned? (4) Is retargeting attribution incremental? (5) Is month-2+ retention/refund-timing data available?

Task 2 — Six campaign analysis

Campaign	CPI	Cost/trial	CAC	Trial→paid	Annual mix	Net ROAS
Meta broad	█15.0	█214	█692	30.9%	21.6%	0.59
Meta lookalike 3%	█9.9	█88	█626	14.0%	8.3%	0.45
Meta retargeting	█29.9	█159	█447	35.5%	30.2%	1.10
Google UAC (actions)	█20.9	█208	█619	33.7%	27.1%	0.74
Google UAC (installs)	█12.4	█207	█766	27.0%	17.2%	0.48
ShareChat video	█8.4	█179	█831	21.5%	8.9%	0.34

Cohort logic: each day-D acquisition cohort receives day-D+1 renewals, annual renewals, plan revenue and refunds. 29 Aug is excluded because day-D+1 is not observed. Totals are summed before ratios are calculated. “First month” here means █1 trial fee + first plan charge – refunds; the file does not contain month-2 data.

Task 3 — Which campaigns actually work?

Rank	Cost per trial	Rank	First-month net ROAS
1	Meta lookalike 3% (■88)	1	Meta retargeting (1.10)
2	Meta retargeting (■159)	2	Google UAC (actions) (0.74)
3	ShareChat video (■179)	3	Meta broad (0.59)
4	Google UAC (installs) (■207)	4	Google UAC (installs) (0.48)
5	Google UAC (actions) (■208)	5	Meta lookalike 3% (0.45)
6	Meta broad (■214)	6	ShareChat video (0.34)

The ranking changes substantially. Cost per trial measures acquisition cost at the trial stage; it does not capture whether the trial converts to paid, which plan is chosen, or refunds. Meta lookalike is cheapest at ■88 per trial but only 14.0% convert and 8.3% of payers choose annual, producing ■0.45 net ROAS; Meta retargeting costs ■159 per trial but produces ■1.10 net ROAS. The more precise conclusion is that **low cost per trial is misleading as a campaign-quality metric**.

Week-to-week steering metric: cohort-matched first-month net ROAS. It shows how much first-month net revenue comes back for each rupee spent, after refunds, and therefore captures the funnel and monetization effects that cost per trial misses. Because it is lagged, CAC and annual mix should be watched alongside it as early diagnostic indicators.

Task 4 — Splitting ■1 crore

Campaign	Current run-rate	Proposed	Modeled trials	Modeled paying	Modeled net rev.
Meta broad	■22.2L	■33.3L	13,500	4,170	■17.0L
Google UAC (actions)	■14.9L	■22.4L	9,299	3,129	■14.4L
Google UAC (installs)	■20.1L	■21.4L	9,992	2,697	■9.8L
Meta lookalike 3%	■23.2L	■14.8L	17,194	2,413	■6.8L
Meta retargeting	■5.5L	■8.2L	4,547	1,616	■7.9L
ShareChat video	■7.8L	■0.0L	0	0	■0.0L
Total		■100.0L	54,532	14,024	■55.9L

Method: “Now” is the last 28 clean acquisition days scaled to 30 days. Expected trials use $\text{trials_now} \times (\text{proposed}/\text{current})^{0.8}$. Expected paying users use each campaign’s 90-day cohort trial→paid. Expected net revenue uses each campaign’s 90-day net first-month revenue per trial. The 0.8 exponent is a transparent planning assumption because the dataset does not support a reliable response curve. Live campaigns are constrained to $0.6\times$ – $1.5\times$ current run-rate to avoid unsupported extrapolation.

Diminishing returns: directionally plausible, size not measurable from this file. Cost per trial rose by similar amounts where spend growth was small and large, so the rise may reflect creative fatigue or price drift rather than saturation. Sensitivity of the plan versus the modeled current mix is +2.1% at exponent 0.6, +5.4% at 0.8 and +9.2% at 1.0. The exact response curve is **not supported by the available data**.

Campaign to pause: ShareChat video. It is last on CAC (■831) and first-month net ROAS (0.34), with 21.5% trial→paid and 8.9% annual mix. I would reverse the pause if a controlled 2–3 week holdout at roughly ■8 lakh shows first-month net ROAS ≥ 0.6 or later retention materially improves cumulative economics.

Headline: modeled first-month net revenue of **■55.9 lakh** on **■1 crore** spend (ROAS ≈ 0.56), versus about **■53.0 lakh** (ROAS ≈ 0.53) for the modeled current mix. The modeled gain is about +5.4%; it is a scenario result, not a guaranteed forecast.

Task 5 — The one chart

Green = spend up, grey = spend down, red = pause. 90-day cohorts; ₹L = ₹ lakh. Source: rasoi_growth_data.csv

One sentence: shift budget toward campaigns with stronger first-month net ROAS and fund those increases from lower-value campaigns; do not use cheap trials as the sole steering signal.
